

# AlgaeOnlineAnalyzer as part of a FerryBox: technical improvements and results for the German Wadden Sea

Dagmar Daehne, Lara Luitjens  
Forschungsstelle Küste

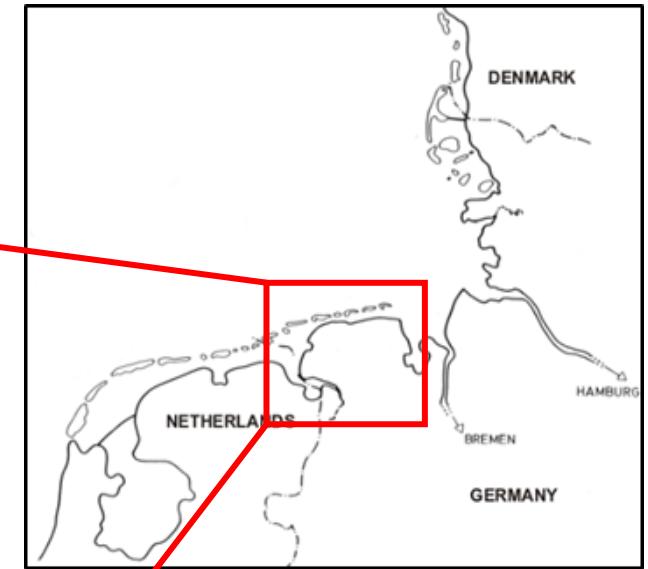

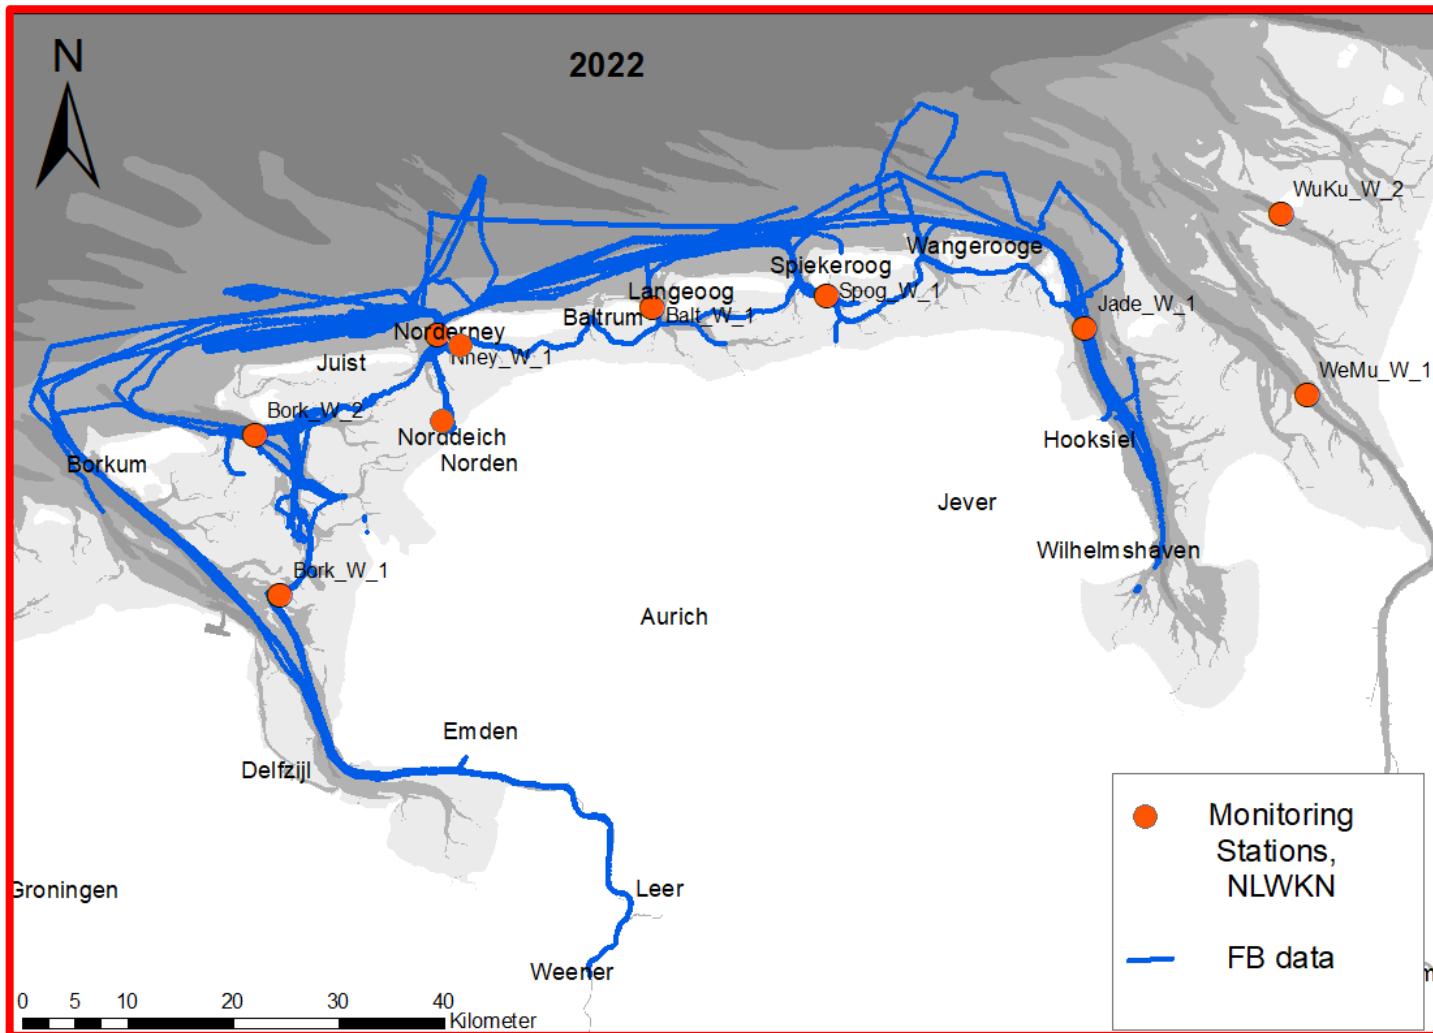

# FerryBox Sensors on RV Burchana

4J JENA  
ENGINEERING

- pH (Meinsberg)
- dissolved oxygen and oxygen saturation (aanderaa)
- temperature and salinity (SeaBird Electronics)
- turbidity (Hach Lange)
- chlorophyll a and algae groups (AlgaeOnlineAnalyzer from bbe Moldaenke)
- pCO<sub>2</sub> (Contros)
- anorganic nutrients (wet-chemistry analyzers from Systea)
- Water Sampler (ICSO) for 24 samples

# Operation Area of RV Burchana

- Wadden Sea between Ems and Weser
- Waterdepth in Wadden Sea 1.5 – 15 m
- high turbidity
- Discharge from Ems und Weser with high nutrient loads
- Monitoring stations for WFD: long term measurements for nutrients, chl a, phytoplankton taxonomy, water quality etc.

# Measurements of Algae Groups

## FerryBox - AlgaeOnlineAnalyzer (bbe moldaenke):

- determines the algae content as *chl a* [ $\mu\text{g/l}$ ] by chlorophyll fluorescence using excitation by light sources (six different LEDs at particular frequencies)
- A complex spectral analysis of characteristic pigments in the algae leads to the allocation of the fluorescence signal to the group of yellow substances (CDOM) and to particular algae groups:

diatoms/flagellates (brown), green algae, blue algae and cryptophyta

## WFD-Monitoring - Taxonomy by a reversal 2D-Microscope (Utermöhl, 1958)

- Long-term measurements since 1999 for taxonomy at determination rank of species
- Determination of abundance by counting, determination of cell volume and biovolume by measuring 2D
- → Estimation of biomass of cellular carbon [ $\mu\text{g/l}$ ] relating to biovolume

## Questions:

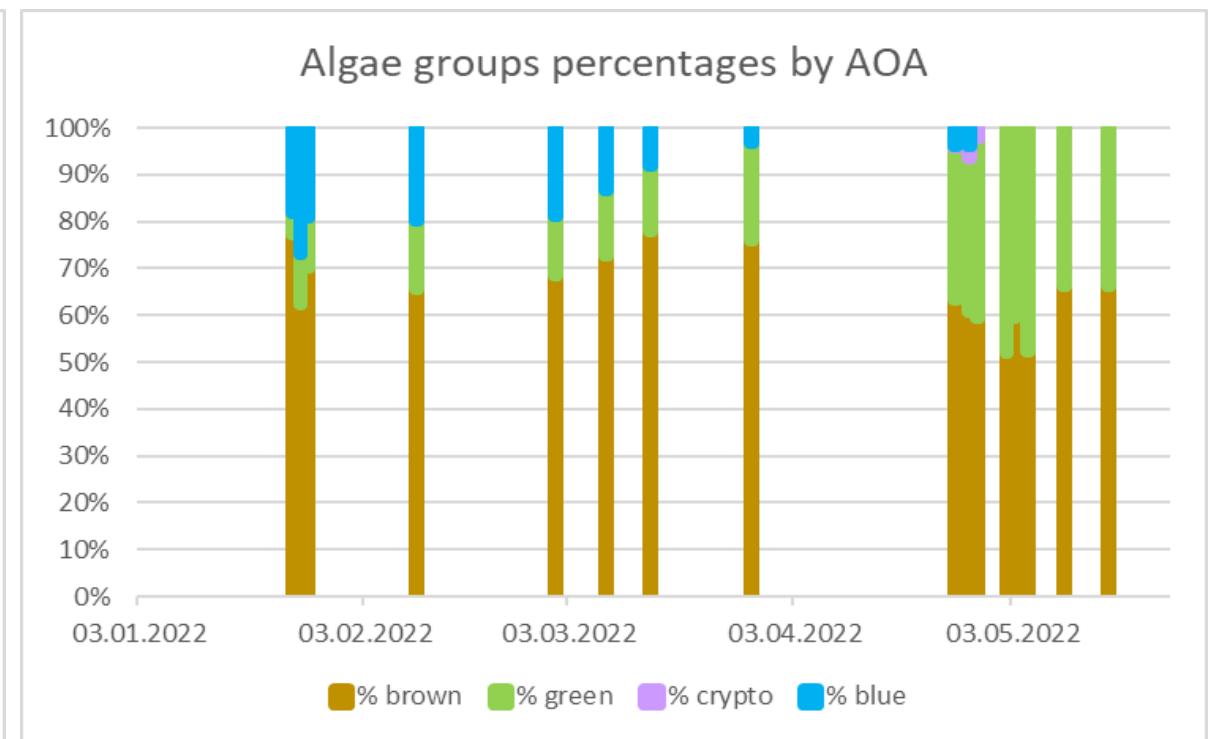

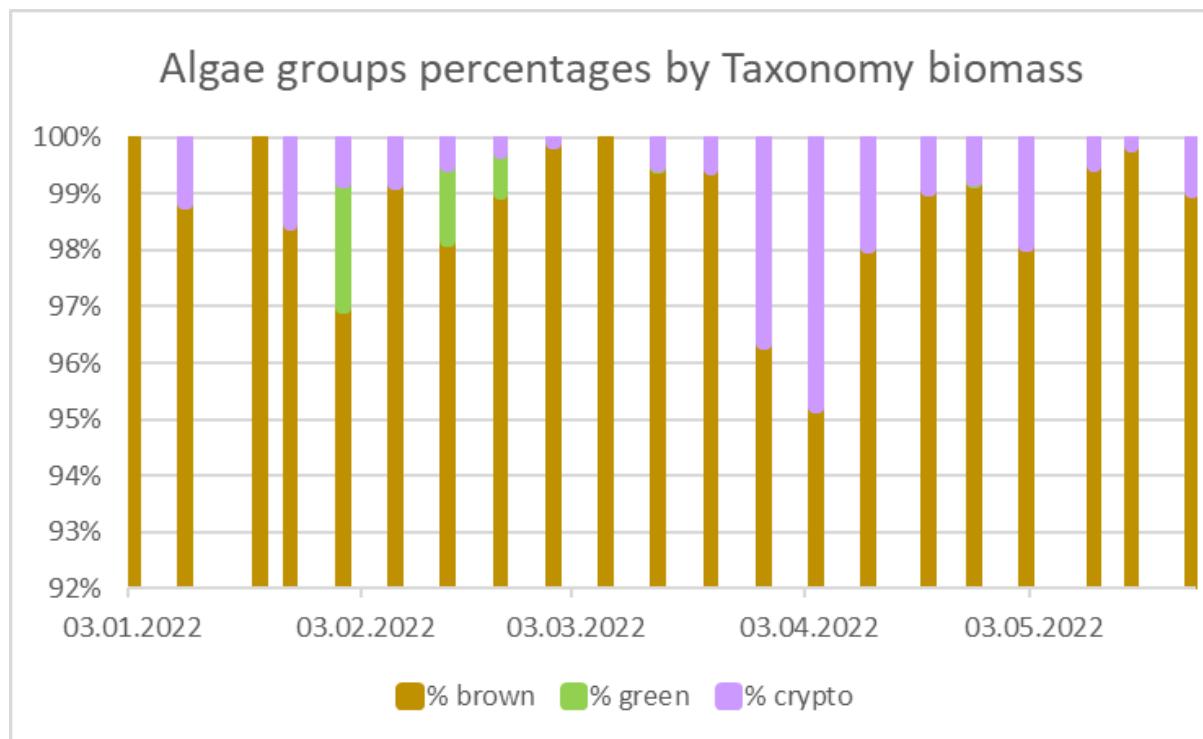

- Are the measurements comparable?
- If yes - HOW?

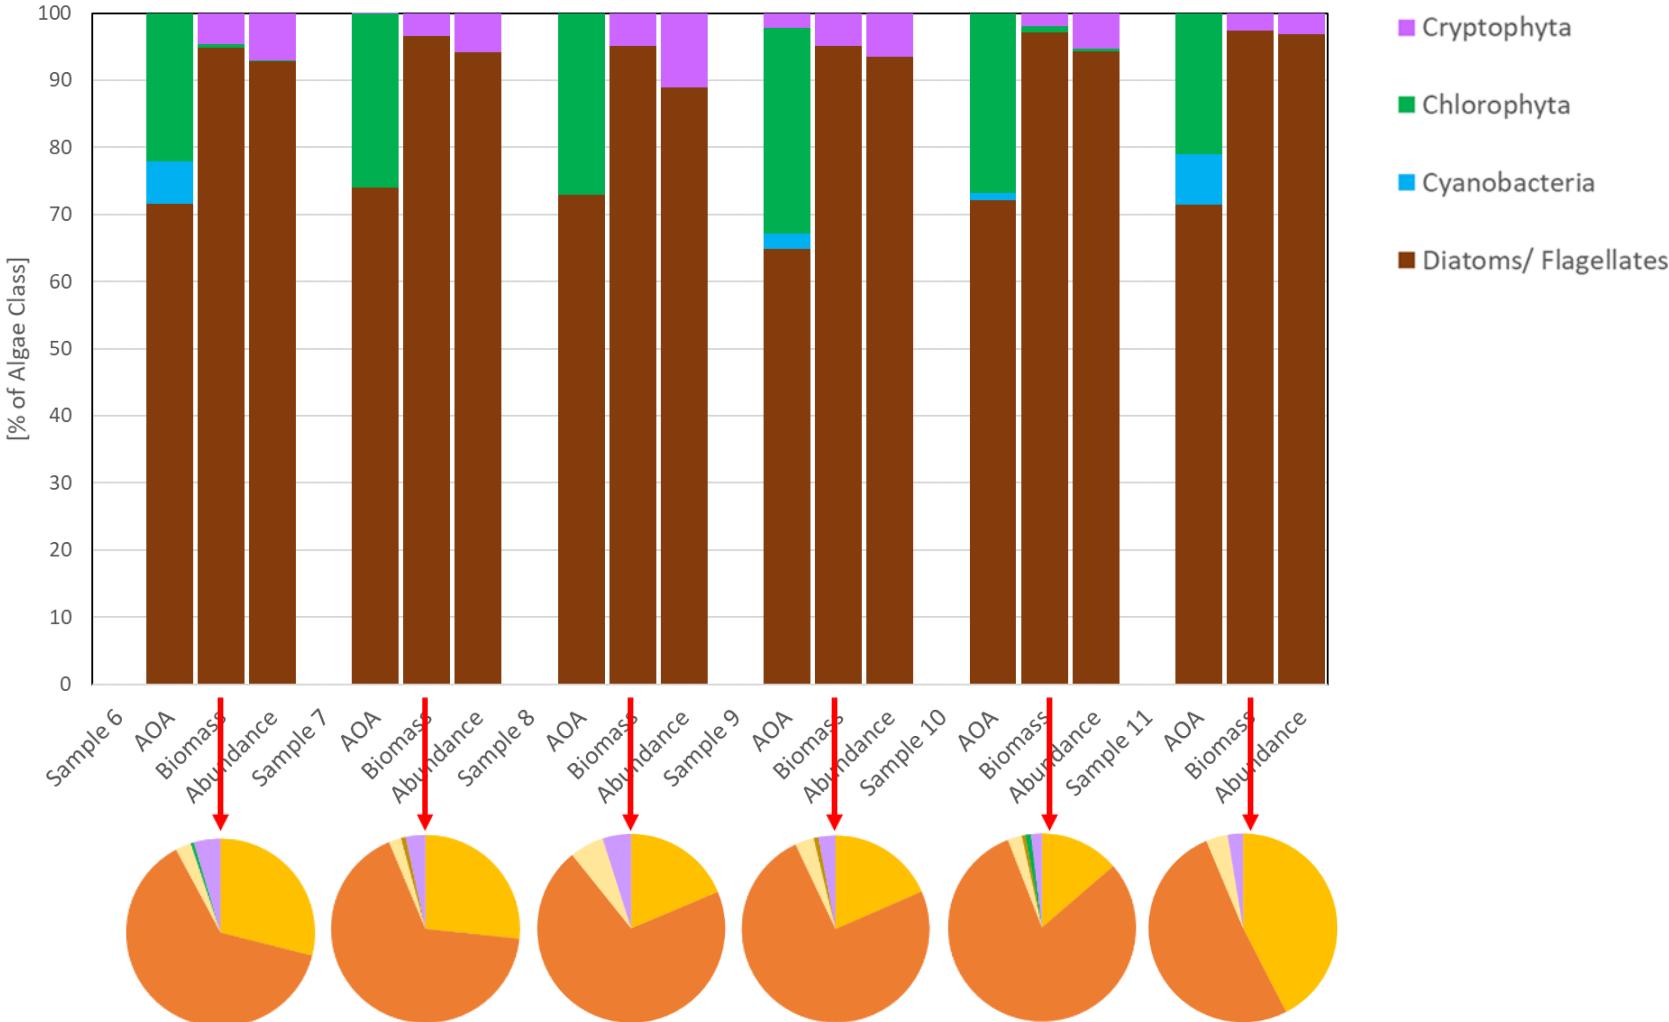

# Comparison of Algae Groups by AOA (factory settings) and Taxonomy

Monitoring Station Norderney Harbour January – May 2022

- Taxonomy sampling station (weekly)
- AOA: different tracks by passing the station due operative business

# Composition of Algae Groups AOA (factory settings) and Taxonomy

21.04.2022:  
Samples 6-11 before bloom of  
*Phaeocystis* sp

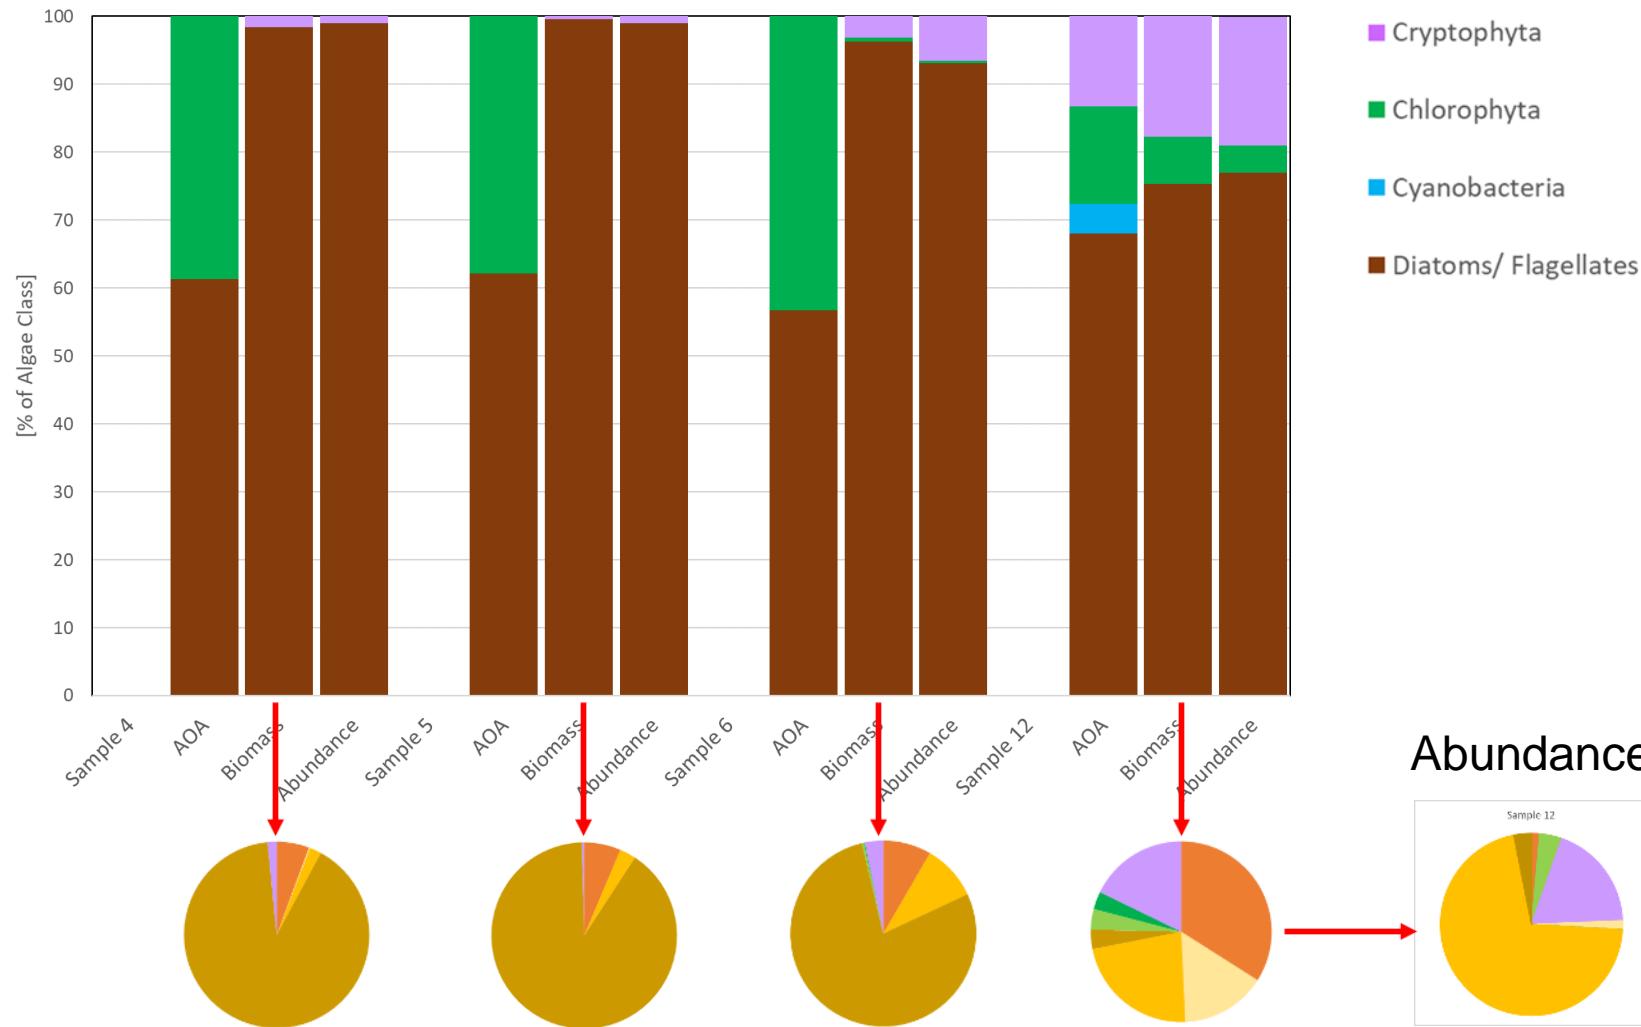

Composition of algae groups  
by chlorophyll a (AOA) and by  
biomass and abundancy  
(Taxonomy)

% biomass of subphylum

Flagellata	Haptophyta
Bacillariophyta	Chlorophyta
Dinophyta	Cryptophyta

# Composition of Algae Groups AOA (factory settings) and Taxonomy

04.05.2020:  
Samples 4-6 during bloom of  
Phaeocystis sp  
02.07.2020:  
Sample 12 after bloom of  
Phaeocystis sp

Composition of algae groups  
by chlorophyll a (AOA) and by  
biomass and abundancy  
(Taxonomy)

## First Results (AOA factory setting)

- Overestimation of chlorophyta, worst results during bloom of Phaeocystis with 40% green algae instead of 0%
- Cryptophyta are not recognized at all, except after algae bloom in summer
- Subphylums of the brown algae group overlay obviously the signal of cryptophyta, but not specifically one of the subphylums
- Cyanobacteria are wrongly recognized, they are not expected in the Wadden Sea. The reason could be that they have a similar fingerprint to yellow substances
- Caution! Taxonomy doesn't capture Nanoplankton and Picoplankton.

→ consulting bbe moldaenke

# Recalibration of AOA

- Factory setting: Calibration of four algae groups

Diatoms: *Cyclotella meneghiniana*

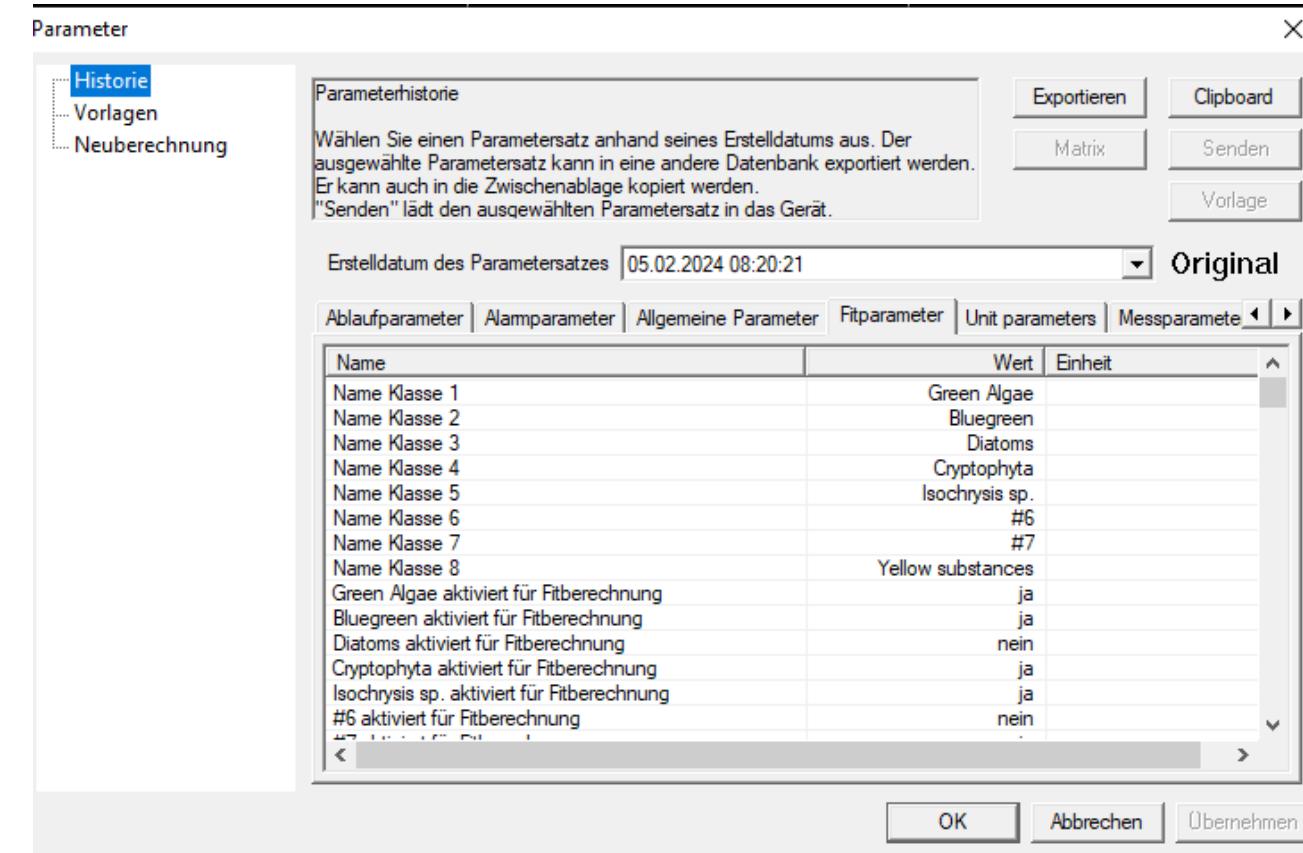

Bluegreen algae: *Microcystis aeruginosa*

Green algae: *Chlorella vulgaris*

Cryptos: *Cryptomonas sp.*

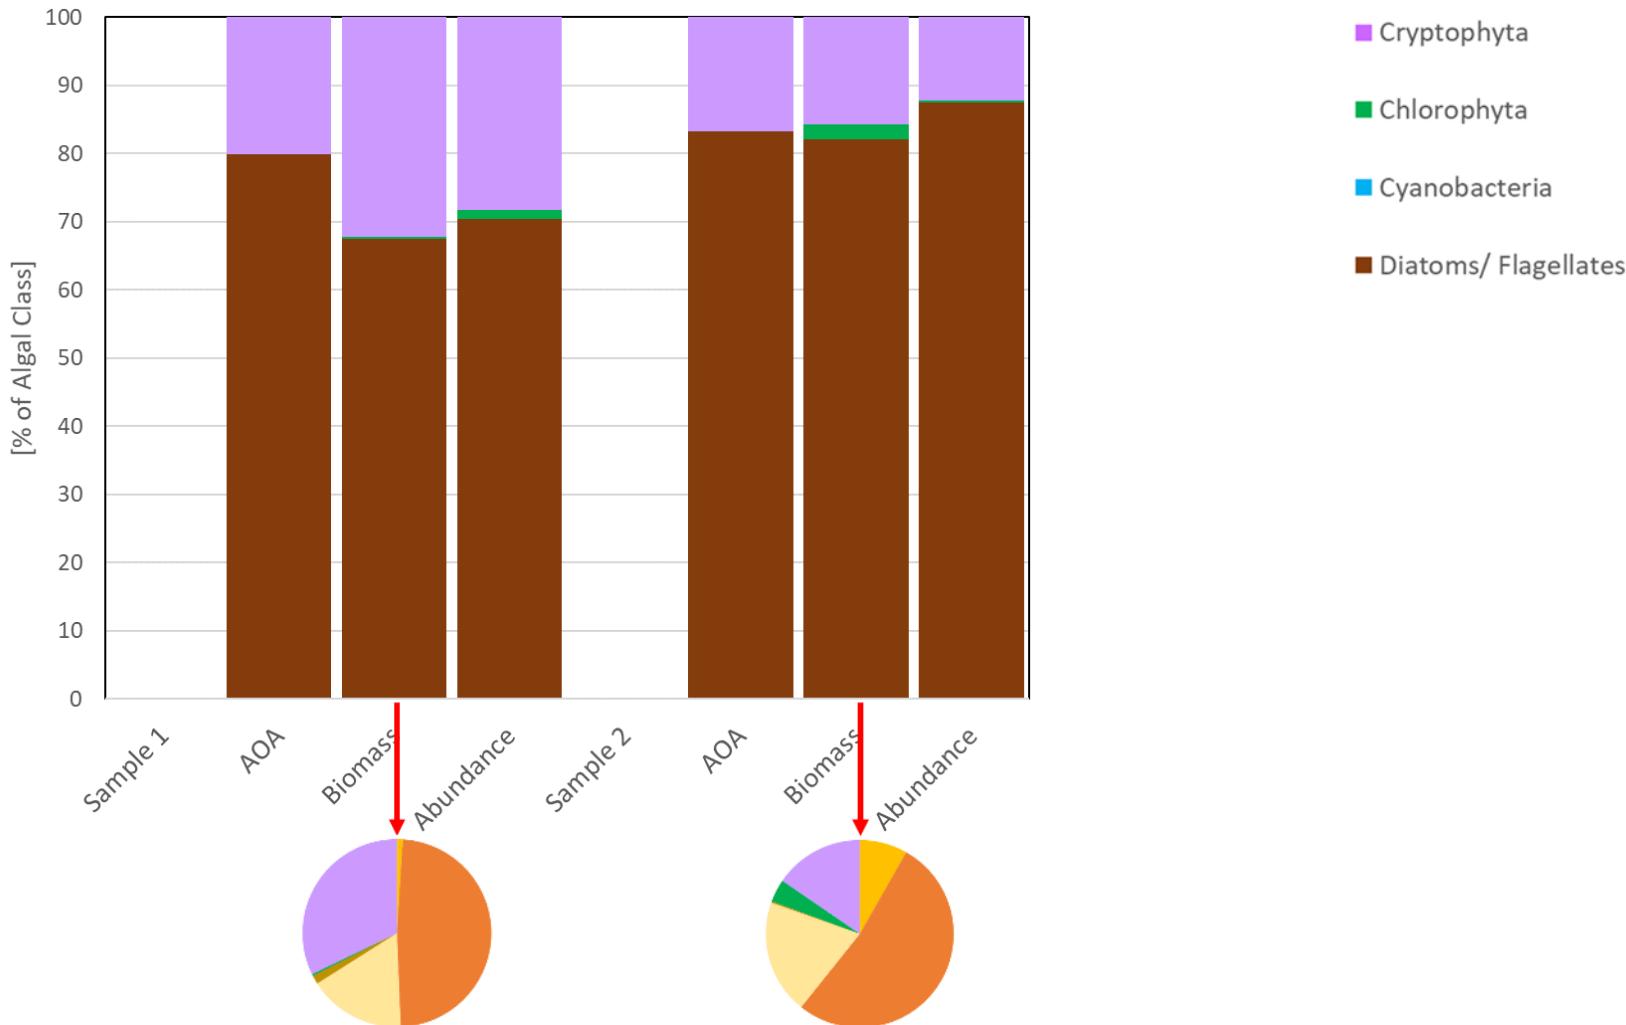

- New: Calibration of *Isochrysis galbana* with a similar fingerprint to *Phaeocystis*

- Software: four classes can be selected for the fitting calculation
  - activate *Isochrysis* instead of diatoms

# Composition of Algae Groups AOA (recalibrated) and Taxonomy

04.07.2024:  
Sample 1-2 after bloom of  
*Phaeocystis* sp

Composition of algae groups  
by chlorophyll a (AOA) and by  
biomass and abundancy  
(Taxonomy)

# Conclusion

- With further calibration of *Isochrysis* and using the fingerprint of *Isochrysis* instead of diatoms in the AOA for the internal fitting calculation we improved the percentages of the different algae groups compared to taxonomy analysis (percentages of diatoms and cryptophyta are in the same order of magnitude of taxonomy now, cyanobacteria are not detected anymore)
- (little) fraction of chlorophyta is not detected
- Further investigations are necessary to assess the composition of algae groups in phytoplankton during the algae bloom

Thank you for  
your attention!
